

HOW AI IS CHANGING STUDENT LIFE IN INDIA

Data Analysis Report

By Ayyam Ullah

Exploratory Data Analysis on AI Adoption Among Indian Students

Dataset: AI_Student_Life_India_2026.csv (5,000 students)

Scope: Age, gender, education level, city, AI tool, usage hours, purpose, grade impact, satisfaction

Date: September 26, 2026

An exploratory analysis of AI tool adoption patterns among Indian students and their relationship with academic outcomes and satisfaction.

Chapter 1

Executive summary

This report examines how Artificial Intelligence tools are being used by Indian students, based on a survey-style dataset of 5,000 student records spanning school, college, and university levels across 29 Indian cities. The analysis covers age, gender balance, education-level split, AI tool preference, daily usage intensity, purpose of use, impact on grades, satisfaction levels, and city-wise adoption. Across nearly every category — age, tool choice, purpose, grade impact, and satisfaction — the dataset shows a strikingly even spread. This is itself a notable finding: at this scale, AI adoption in India does not appear concentrated around any single tool, purpose, or outcome, but is broad-based across the student population.

Chapter 2

Context and scope

2.1 Business question

How widespread and varied is AI tool usage among Indian students, and is there any discernible relationship between how much AI students use and their reported academic and satisfaction outcomes?

2.2 Dataset overview

The dataset contains 5,000 student records with no missing values, across ten fields: Student ID, Age (15–25), Gender, Education Level (School / College / University), City, AI Tool Used, Daily Usage Hours (0.5–6.5), Purpose, Impact on Grades, and Satisfaction Level.

2.3 Success criteria

- Establish the demographic composition of the surveyed students;
- Identify which AI tools are most widely used and for what purposes;
- Characterize daily usage intensity and how it varies by education level;
- Examine whether usage intensity correlates with reported grade impact or satisfaction;
- Identify the cities with the highest AI adoption.

Chapter 3

Graphical analysis

3.1 Age distribution

Ages range from 15 to 25, with counts for each individual age fairly evenly spread across the full range rather than clustering around a particular age group.

Figure 3.1: Age distribution of surveyed students (each bar represents one age from 15 to 25).

3.2 Daily usage patterns

Daily usage ranges from 0.5 to 6.5 hours, with a mean of about 3.5 hours and a fairly even spread across that range (no strong peak at either the low or high end). This indicates a wide variety of engagement levels rather than a single typical usage pattern.

Figure 3.2: Distribution of daily AI usage hours.

3.3 Gender distribution

The sample is close to evenly split, with a slight majority of female students (2,572) over male students (2,428) — a 51.4% / 48.6% split.

Figure 3.3: Gender distribution of surveyed students, shown as a bar chart and a pie chart.

3.4 Education level

Students are almost evenly distributed across School (1,674), University (1,665), and College (1,661), meaning no single education stage dominates the dataset.

Figure 3.4: Distribution of students by education level.

3.5 AI tool adoption

All seven AI tools — Copilot, Gemini, Notion AI, Perplexity, ChatGPT, Grammarly, and Claude — are used by a comparable number of students (696 to 735 each). No single platform dominates; adoption is broad-based rather than concentrated around one or two market leaders.

Figure 3.5: Number of students using each AI tool.

3.6 Primary purpose of use

Writing (1,030), Learning (1,026), Research (994), Homework (979), and Coding (971) are all used by roughly similar numbers of students. AI is being used across the full spectrum of academic tasks rather than for one dominant purpose.

Figure 3.6: Primary purpose of AI tool usage among students.

3.7 Impact on grades

Reported grade impact splits almost exactly into thirds: Slight Decline (1,675), No Change (1,669), and Improved (1,656). There is no dominant outcome — roughly equal numbers of students report each result.

Figure 3.7: Reported impact of AI usage on grades.

3.8 Satisfaction level

Satisfaction with AI tools is also split almost evenly across Low (1,668), Medium (1,666), and High (1,666), showing no clear overall lean toward satisfaction or dissatisfaction at the population

level.

Figure 3.8: Student satisfaction levels with AI tools.

3.9 Top cities by adoption

Lucknow (206), Jaipur (201), Mumbai (193), Vijayawada (190), and Pune (185) have the highest number of AI-using students in the dataset, though the gap between the top and mid-ranking cities is small, suggesting adoption is fairly evenly spread across the 29 cities surveyed rather than concentrated in a few metro hubs.

Figure 3.9: Top 5 cities by number of AI-using students, shown as a bar chart and a pie chart.

3.10 Gender across AI tools

Breaking tool usage down by gender shows a broadly consistent pattern: no AI tool is disproportionately favored by one gender over the other, reinforcing that tool choice is not gender-driven

in this dataset.

Figure 3.10: Gender distribution across each AI tool.

Chapter 4

Dashboard

The figure below consolidates all twelve analyses into a single dashboard view for quick reference.

Figure 4.1: Consolidated dashboard: How AI Is Changing Student Life in India.

Chapter 5

Key insights

1. **Balanced demographics:** The sample is close to evenly split by gender (51.4% female / 48.6% male) and by education level (School, College, University each roughly one-third), giving a representative cross-section of Indian students.
2. **Even age spread:** Students aged 15 through 25 are represented in roughly similar numbers, with no single age group standing out.
3. **No dominant AI tool:** Adoption is spread almost evenly across seven major AI tools, indicating Indian students are exploring a wide range of platforms rather than converging on one market leader.
4. **Broad-based usage purposes:** Writing, Learning, Research, Homework, and Coding are used in roughly equal measure, showing AI has been integrated across the full range of academic tasks rather than one narrow use case.
5. **Moderate average usage:** Students use AI for about 3.5 hours per day on average, with usage fairly evenly spread from half an hour to over six hours — there is no single “typical” usage pattern.
6. **Mixed and even grade impact:** Reported impact on grades splits almost exactly into thirds (Improved / No Change / Slight Decline), and average usage hours are nearly identical across all three groups (3.41–3.56 hours) — in this dataset, usage intensity alone does not clearly predict grade outcome.
7. **Even satisfaction split:** Satisfaction levels (Low / Medium / High) are also nearly equal, suggesting no dataset-wide consensus on whether AI tools are meeting student expectations.
8. **Adoption spread across cities:** While Lucknow, Jaipur, Mumbai, Vijayawada, and Pune lead in raw student counts, the gap to other cities is modest, pointing to nationwide rather than metro-concentrated adoption.
9. **Note on data structure:** The near-uniform distribution across almost every categorical and numeric field suggests this dataset may be synthetically generated rather than drawn from organic survey responses. This does not diminish its usefulness for practicing analysis techniques, but conclusions about real-world causal relationships (e.g. “does more AI usage hurt grades?”) should be drawn cautiously.
